Misc

Template

```cpp
//#pragma GCC optimize("Ofast")
#include <bits/stdc++.h>
#define all(x) begin(x),end(x)
using namespace std;
using ll = long long;
int main() {
    ios_base::sync_with_stdio(false);
    cin.tie(nullptr);
}
```

Compilation Script

```bash
#!/bin/bash
g++ --std=c++17 -Wall -Wshadow -Wno-conversion -ftrapv -g $1 -o ${1%.cpp}.bin
```

Polynomial Hash

```cpp
using lll = __int128_t;
ll P = 12233720368547789LL;
ll B = 260;
struct PolyHash {
    vector<ll> hashes, ex;
    PolyHash(const string& s) : hashes(s.size() + 1), ex(s.size() + 1) {
        hashes[0] = 1; ex[0] = 1; ex[1] = B;
        for (size_t i = 0; i < s.size(); i++) {
            hashes[i + 1] = ((hashes[i] * B) % P + s[i] + 1) % P;
            ex[i + 1] = (ex[i] * B) % P;
        }
    }
    ll hash(ll lo, ll hi) {
        return ((lll)hashes[hi] - (lll)hashes[lo] * (lll)ex[hi - lo] % P + P) % P;
    }
};
```

Binary Search

```cpp
while (lo < hi) {
    ll mid = lo + (hi - lo) / 2;
    if (f(mid)) // f should be false, then true
        hi = mid;
    else
        lo = mid + 1;
}
//lo is now the first index where f is true
```

Ternary Search

Find the smallest i in $[a, b]$ that maximizes $f(i)$, assuming that $f(a) < \cdots < f(i) \geq \cdots \geq f(b)$.

If there is a range of $f(i) \ldots f(j)$ that are equal, change according to the comments to get the last index instead of the first.

```cpp
template<class F>
ll ternarySearch(ll a, ll b, F f) {
    assert(a <= b);
    while (b - a >= 5) {
        ll mid = (a + b) / 2;
        if (f(mid) < f(mid+1)) // <= for last index
            a = mid;
        else
            b = mid+1;
    }
    //for (ll i = b; i > a; i--) to get last index
    for (ll i = a + 1; i <= b; i++)
        if (f(a) < f(i))
            a = i;
    return a;
}
```

```python
def ternarySearch(a, b, f):
    assert a <= b
    while b - a >= 5:
        mid = (a + b) // 2
        if f(mid) < f(mid+1): # <= for last index
            a = mid
        else:
            b = mid + 1
    #for i in range(b, a-1, -1): to get last index
    for i in range(a+1, b+1):
        if f(a) < f(i):
            a = i
    return a
```

Geometry

Geometry Template (Python)

```python
def vecsub(a, b):
    return (a[0] - b[0], a[1] - b[1])
def vecadd(a, b):
    return (a[0] + b[0], a[1] + b[1])
def dot(a, b):
    return a[0] * b[0] + a[1] * b[1]
def cross(a, b, o = (0, 0)):
    return (a[0] - o[0]) * (b[1] - o[1]) - (a[1] - o[1]) * (b[0] - o[0])
def len2(a):
    return a[0] ** 2 + a[1] ** 2
def dist2(a, b):
    return len2(vecsub(a, b))
def sign(x):
    return (x > 0) - (x < 0)
def zero(x):
    return abs(x) < 1E-9
```

Geometry Template (C++)

```cpp
template <typename T> struct point {
    T x, y;
    point() { x=y=0; }
    point(T xx, T yy) : x(xx), y(yy) { }
    template <typename U> point(point<U> o) : x(o.x), y(o.y) { }
    point operator+(point o) const { return { x+o.x, y+o.y }; }
    point operator-(point o) const { return { x-o.x, y-o.y }; }
    point operator*(T o) const { return { x*o, y*o }; }
    point operator/(T o) const { return { x/o, y/o }; }
    bool operator==(point o) const { return x==o.x && y==o.y; };
    bool operator<(point o) const { return tie(x, y) < tie(o.x, o.y); };
    T dot(point o) const { return x*o.x + y*o.y; }
    T cross(point b) const { return x*b.y - y*b.x; }
    T cross(point b, point o) const { return (*this-o).cross(b-o); }
    T len2() const { return x*x + y*y; }
};
using ipoint = point<ll>;
using dpoint = point<double>;
ll sign(auto x) { return (x>0) - (x<0); }
bool zero(double x) { return abs(x) < 1E-9; }
```

Check if point is on a line segment

```python
def onSegment(s, e, p):
    # return zero(distPS(s, e, p))   if floating-point is OK
    return cross(s, e, p) == 0 and dot(vecsub(s, p), vecsub(e, p)) <= 0
```

```cpp
bool onSegment(ipoint s, ipoint e, ipoint p) { return s.cross(e, p) == 0 && (s - p).dot(e - p) <= 0; }
```

Distance between point and line segment

Returns the distance from the point p to the line segment starting at s and ending at e.

```cpp
double distPS(ipoint s, ipoint e, ipoint p) {
    if (s == e)
        return sqrt((p - s).len2());
    auto se = e - s;
    auto sp = p - s;
    ll d = se.len2();
    ll t = min(d, max(0LL, (p - s).dot(e - s)));
    return sqrt((sp * d - se * t).len2()) / d;
}
```

```python
def distPS(s, e, p):
    if s == e:
        return sqrt(dist2(p, s))
    se, sp = vecsub(e, s), vecsub(p, s)
    d = len2(se)
    t = min(d, max(0, dot(vecsub(p,s), vecsub(e,s))))
    return sqrt(dist2(
        (sp[0]*d, sp[1]*d),
        (se[0]*t, se[1]*t)
    )) / d
```

Distance between point and line

Returns the signed distance from the point p to the line passing through the points a and b.

```cpp
double distPL(ipoint a, ipoint b, ipoint p) {
    return b.cross(p, a) / sqrt((a - b).len2());
}
```

```python
def distPL(a, b, p):
    return cross(b, p, a) / sqrt(dist2(a, b))
```

Project point to line (or reflect)

Projects the point p onto the line passing through a and b. Set `refl=True` to get reflection of point p across the line instead.

```cpp
dpoint projPL(ipoint a, ipoint b, ipoint p, bool
    ↪ refl = false) {
    auto v = b - a;
    double s = (1 + refl) * b.cross(p, a) / v.len2();
    return { p.x + v.y * s, p.y - v.x * s };
}
```

```python
def projPL(a, b, p, refl = False):
    v = vecsub(b, a)
    s = (1 + refl) * cross(b, p, a) / len2(v)
    return (p[0] + v[1] * s, p[1] - v[0] * s)
```

Intersection between two lines

If a unique intersection point of the lines going through `s1,e1` and `s2,e2` exists (`1,point`) is returned.
If no intersection point exists (`0,(0,0)`) is returned and if infinitely many exist (`-1,(0,0)`) is returned.

```cpp
pair<int, dpoint> intersectLL(ipoint s1, ipoint e1,
    ↪ ipoint s2, ipoint e2) {
    auto d = (e1 - s1).cross(e2 - s2);
    if (zero(d)) # parallel
        return { -int(zero(e1.cross(s2, s1))), {} };
    auto p = e1.cross(e2, s2);
    auto q = e2.cross(s1, s2);
    return { 1, dpoint(
        (s1.x * p + e1.x * q),
        (s1.y * p + e1.y * q)
    ) / d };
}
```

```python
def intersectLL(s1, e1, s2, e2):
    d = cross(vecsub(e1, s1), vecsub(e2, s2))
    if zero(d): # parallel
        return (-zero(cross(e1, s2, s1)), (0, 0))
    p, q = cross(e1, e2, s2), cross(e2, s1, s2)
    return (1,(
        (s1[0] * p + e1[0] * q) / d,
        (s1[1] * p + e1[1] * q) / d
    ))
```

Intersection between two line segments

If a unique intersection is found, returns a list with only this point. If the segments intersect in many points, returns a list of 2 elements containing the start and end of the common line segment. If no intersection, returns an empty list

```cpp
vector<dpoint> intersectSS(ipoint s1, ipoint e1,
    ↪ ipoint s2, ipoint e2) {
    auto oa = e2.cross(s1, s2);
    auto ob = e2.cross(e1, s2);
    auto oc = e1.cross(s2, s1);
    auto od = e1.cross(e2, s1);
    if (sign(oa)*sign(ob)<0 && sign(oc)*sign(od)<0) {
        return { dpoint(s1.x * ob - e1.x * oa,
                        s1.y * ob - e1.y * oa)
                    / double(ob - oa) };
    }
    set<ipoint> s;
    if (onSegment(s2, e2, s1)) s.insert(s1);
    if (onSegment(s2, e2, e1)) s.insert(e1);
    if (onSegment(s1, e1, s2)) s.insert(s2);
    if (onSegment(s1, e1, e2)) s.insert(e2);
    return {all(s)};
}
```

```python
def intersectSS(s1, e1, s2, e2):
    oa = cross(e2, s1, s2)
    ob = cross(e2, e1, s2)
    oc = cross(e1, s2, s1)
    od = cross(e1, e2, s1)
    if sign(oa)*sign(ob)<0 and sign(oc)*sign(od)<0:
        div = ob - oa
        return [(
            (s1[0] * ob - e1[0] * oa) / div,
            (s1[1] * ob - e1[1] * oa) / div
        )]
    s = set()
    if onSegment(s2, e2, s1): s.add(s1)
    if onSegment(s2, e2, e1): s.add(e1)
    if onSegment(s1, e1, s2): s.add(s2)
    if onSegment(s1, e1, e2): s.add(e2)
    return list(s)
```

Polygon area

Returns twice the signed area of a polygon. Clockwise enumeration gives negative area.

```cpp
ll polygonArea2(const vector<ipoint>& v) {
    ll a = 0;
    for (ll i = 0; i < (ll)v.size(); i++)
        a += v[i].cross(v[(i+1) % v.size()]);
    return a;
}
```

```python
def polygonArea2(v):
    return sum(map(lambda i: cross(v[i - 1], v[i]),
        ↪ range(len(v))))
```

Point inside polygon

Returns true if the point `pt` lies within the polygon `poly`. If strict is true, returns false for points on the boundary.

```python
def pointInPolygon(poly, pt, strict = True):
    c = False
    for i in range(len(poly)):
        q = poly[i - 1]
        if onSegment(q, poly[i], pt):
            return not strict
        c ^= ((pt[1] < q[1]) - (pt[1] < poly[i][1])) * cross(q, poly[i], pt) > 0
    return c
```

```cpp
bool pointInPolygon(const vector<ipoint>& poly, ipoint p, bool strict = true) {
    bool c = false;
    auto prev = poly.back();
    for (auto cur : poly) {
        if (onSegment(prev, cur, p)) return !strict;
        c ^= ((p.y < prev.y) - (p.y < cur.y)) * prev.cross(cur, p) > 0;
        prev = cur;
    }
    return c;
}
```

Intersection between two circles

Computes the pair of points at which two circles intersect. Returns `None` in case of no intersection.

```cpp
template <typename T> optional<array<dpoint, 2>>
intersectCC(point<T> c1, point<T> c2, T r1, T r2) {
    if (c1 == c2) {
        assert(r1 != r2);
        return { };
    }
    auto vec = c2 - c1;
    T d2 = vec.len2(), sm = r1 + r2, dif = r1 - r2;
    if (sm * sm < d2 || dif * dif > d2)
        return { };
    double p = double(d2 + r1*r1 - r2*r2) / (d2 * 2);
    dpoint mid(c1.x + vec.x * p, c1.y + vec.y * p);
    dpoint per = dpoint(-vec.y, vec.x) *
    ↪ sqrt(max(0.0, r1 * r1 - p * p * d2) / d2);
    return { { mid+per, mid-per } };
}
```

```python
def intersectCC(c1, c2, r1, r2):
    if c1 == c2:
        assert(r1 != r2)
        return None
    vec = vecsub(c2, c1)
    d2 = len2(vec)
    if (r1 + r2) ** 2 < d2 or (r1 - r2) ** 2 > d2:
        return None
    p = (d2 + r1 ** 2 - r2 ** 2) / (d2 * 2)
    h2 = r1 ** 2 - p * p * d2
    mid = (c1[0] + vec[0] * p, c1[1] + vec[1] * p)
    plen = sqrt(max(0, h2) / d2)
    per = (-vec[1] * plen, vec[0] * plen)
    return (vecadd(mid, per), vecsub(mid, per))
```

Intersection between circle and line

Computes the intersection between a circle and a line. Returns a list of either 0, 1, or 2 intersection points.

```cpp
vector<dpoint> intersectCL(dpoint c, double r,
    ↪ dpoint a, dpoint b) {
    dpoint ab = b - a;
    dpoint p = a + ab * (c-a).dot(ab) / ab.len2();
    double s = a.cross(b, c);
    double h2 = r*r - s*s / ab.len2();
    if (h2 < 0) return {};
    if (h2 == 0) return {p};
    dpoint h = ab * sqrt(h2 / ab.len2());
    return {p - h, p + h};
}
```

```python
def intersectCL(c, r, a, b):
    ab = vecsub(b, a)
    ps = dot(vecsub(c, a), ab) / len2(ab)
    p = (a[0] + ab[0] * ps, a[1] + ab[1] * ps)
    h2 = r ** 2 - cross(a, b, c) ** 2 / len2(ab)
    if h2 < 0: return []
    if h2 == 0: return [p]
    h2 = sqrt(h2 / ab.len2())
    h = (ab[0] * h2, ab[1] * h2);
    return [vecsub(p, h), vecadd(p, h)]
```

Circumcircle

Returns a circle from three points.

```cpp
pair<dpoint, double> circumcirle(array<dpoint,3> p) {
    auto b = p[2] - p[0], c = p[1] - p[0];
    double bc = b.cross(c);
    assert(!zero(bc)); // collinear
    auto x = b * c.len2() - c * b.len2();
    dpoint rc = dpoint(-x.y, x.x) / bc;
    return { p[0] + rc, sqrt(rc.len2()) };
}
```

```python
def circumcirle(p1, p2, p3):
    b, c = vecsub(p3, p1), vecsub(p2, p1)
    bc, c2, b2 = cross(b, c) * 2, len2(c), len2(b)
    assert not zero(bc) # collinear
    rc = ((c[1]*b2 - b[1]*c2)/bc,
          (b[0]*c2 - c[0]*b2)/bc)
    return (vecadd(p1,rc), sqrt(len2(rc)))
```

Circle-polygon area

Returns the area of the intersection of a circle with a counter-clockwise polygon. Time complexity: $\mathcal{O}(n)$

```
double circlePolyArea(dpoint c, double r, vector<dpoint> ps) {
    auto arg = [&](dpoint p, dpoint q) { return atan2(p.cross(q), p.dot(q)); };
    auto tri = [&](dpoint p, dpoint q) {
        double r2 = r * r / 2;
        dpoint d = q - p;
        double a = d.dot(p)/d.len2(), b = (p.len2()-r*r)/d.len2();
        double det = a * a - b;
        if (det <= 0) return arg(p, q) * r2;
        auto s = max(0., -a-sqrt(det)), t = min(1., -a+sqrt(det));
        if (t < 0 || 1 <= s) return arg(p, q) * r2;
        dpoint u = p + d * s, v = p + d * t;
        return arg(p,u) * r2 + u.cross(v)/2 + arg(v,q) * r2;
    };
    double sum = 0.0;
    for (size_t i = 0; i < ps.size(); i++)
        sum += tri(ps[i] - c, ps[(i + 1) % ps.size()] - c);
    return sum;
}
```

Circle tangents

Finds the external tangents of two circles, or internal if r2 is negated.
Can return 0, 1, or 2 tangents – 0 if one circle contains the other (or overlaps it, in the internal case, or if the circles are the same); 1 if the circles are tangent to each other (in which case .first = .second and the tangent line is perpendicular to the line between the centers). .first and .second give the tangency points at circle 1 and 2 respectively. To find the tangents of a circle with a point set r2 to 0.

```
vector<pair<dpoint, dpoint>> circleTangents(dpoint
    ↪ c1, double r1, dpoint c2, double r2) {
    dpoint d = c2 - c1, dp = {-d.y, d.x};
    double dr = r1 - r2, d2 = d.len2();
    double h2 = d2 - dr * dr;
    if (d2 == 0 || h2 < 0)  return {};
    vector<pair<dpoint, dpoint>> out;
    for (double s : {-1, 1}) {
        dpoint v = (d * dr + dp * sqrt(h2) * s) / d2;
        out.push_back({c1 + v * r1, c2 + v * r2});
    }
    if (h2 == 0) out.pop_back();
    return out;
}
```

```
def circleTangents(c1, r1, c2, r2):
    d = vecsub(c2, c1)
    dr, d2 = r1 - r2, len2(d)
    h2, s1, s2 = d2 - dr**2, r1 / d2, r2 / d2
    if d2 == 0 or h2 < 0: return []
    out = []
    for s in [-1, 1]:
        vx = d[0] * dr - d[1] * sqrt(h2) * s
        vy = d[1] * dr + d[0] * sqrt(h2) * s
        out.append((vecadd(c1, (vx*s1, vy*s1)),
                    vecadd(c2, (vx*s2, vy*s2))))
    if h2 == 0: out.pop()
    return out
```

Convex hull

Returns a list of points on the convex hull in counter-clockwise order. Points on the edge of the hull between two other points are not considered part of the hull. Time complexity: $\mathcal{O}(n \log n)$

```
auto convexHull(vector<ipoint> pts) {
    if (pts.size() <= 1) return pts;
    sort(all(pts));
    decltype(pts) h;
    auto f = [&] (ll s) {
        for (auto p : pts) {
            while ((ll)h.size() >= s + 2 &&
    ↪ h.back().cross(p, h[h.size() - 2]) <= 0)
                h.pop_back();
            h.push_back(p);
        }
        h.pop_back();
    };
    f(0);
    reverse(all(pts));
    f(h.size());
    if (h.size() == 2 && h[0] == h[1]) h.pop_back();
    return h;
}
```

```
def convexHull(pts):
    if len(pts) <= 1:
        return pts
    pts.sort()
    t, s, h = 0, 0, [0] * (len(pts) + 1)
    for i in range(2):
        for p in pts:
            while t >= s + 2 and cross(h[t - 1], p,
    ↪ h[t - 2]) <= 0:
                t -= 1
            h[t], t = p, t + 1
        s = t = t - 1
        pts.reverse()
    return h[:t - (t == 2 and h[0] == h[1])]
```

Data Structures

Segment Tree

```cpp
struct SegTree {
    using T = ll;
    T f(T a, T b) { return a + b; }
    static constexpr T UNIT = 0;//neutral value for f

    vector<T> s; ll n;
    SegTree(ll len) : s(2 * len, UNIT), n(len) {}
    void set(ll pos, T val) {
        for (s[pos += n] = val; pos /= 2;)
            s[pos] = f(s[pos * 2], s[pos * 2 + 1]);
    }
    T query(ll lo, ll hi) { // hi not included
        T ra = UNIT, rb = UNIT;
        for (lo+=n, hi+=n; lo < hi; lo/=2, hi/=2) {
            if (lo % 2) ra = f(ra, s[lo++]);
            if (hi % 2) rb = f(s[--hi], rb);
        }
        return f(ra, rb);
    }
};
```

```python
class SegTree:
    def f(a, b):
        return a + b
    UNIT = 0 # neutral value for f

    def __init__(self, n):
        self.s = [self.UNIT] * (2 * n)

```

Fenwick Tree

```cpp
struct FenwickTree {
    FenwickTree(ll n) : v(n + 1, 0) { }
    ll lsb(ll x) { return x & (-x); }
    ll prefixSum(ll n) { //sum of the first n items (nth not included)
        ll sum = 0;
        for (; n; n -= lsb(n))
            sum += v[n];
        return sum;
    }
    void adjust(ll i, ll delta) {
        for (i++; i < v.size(); i += lsb(i))
            v[i] += delta;
    }
    vector<ll> v;
};
```

Sparse Table

```cpp
struct SparseTable {
    using T = ll;
    ll node(ll l, ll i) { return i + l * n; }
    ll n; vector<T> v;
    SparseTable(vector<T> values) : n(values.size()), v(move(values)) {
        ll d = log2(n);
        v.resize((d + 1) * n);
        for (ll L = 0, s = 1; L < d; L++, s *= 2) {
            for (ll i = 0; i < n; i++) {
                v[node(L + 1, i)] = min(v[node(L, i)], v[node(L, min(i + s, n - 1))]);
            }
        }
    }
    T query(ll lo, ll hi) { assert(hi > lo);
        ll l = (ll)log2(hi - lo);
        return min(v[node(l, lo)], v[node(l, hi - (1 << l))]);
    }
};
```

Lazy Segment Tree

Segment tree with support for range updates. Use T = pair of value and index to get index from queries.
All ranges are (lo, hi] (hi is not included). fQuery defines the function to be used for queries (currently min) and fUpdate defines
the function to be used for updates (currently addition).

```cpp
struct LazyST {
    using T = ll;
    T f(T a, T b) { return min(a, b); }
    static const T QUERY_UNIT = LLONG_MAX; // neutral value for f

    struct Node {
        T val = QUERY_UNIT; // current value of this segment
        optional<T> p; // value being pushed down into this segment
    };
    int len; vector<Node> nodes;
    LazyST(int l) : len(pow(2, ceil(log2(l)))), nodes(len * 2) { }
    void update(int lo, int hi, T val) { u(lo, hi, val, 1, 0, len); }
    T query(int lo, int hi) { return q(lo, hi, 1, 0, len); }
private:
    #define LST_NEXT int l = n * 2; int r = l + 1; int mid = (nlo + nhi) / 2
    void push(int n, int nlo, int nhi) {
        if (!nodes[n].p) return;
        LST_NEXT;
        u(nlo, nhi, *nodes[n].p, l, nlo, mid);
        u(nlo, nhi, *nodes[n].p, r, mid, nhi);
        nodes[n].p = {};
    }
    void u(int qlo, int qhi, T val, int n, int nlo, int nhi) {

45         trRecount(r);
46         return r;
47     }
48 }
49 // inserts the treap n into t at index pos (or value pos, depending on implementation of trSplit)
50 Treap* trInsert(Treap* t, Treap* n, int pos) {
51     auto pa = trSplit(t, pos);
52     return trJoin(trJoin(pa.first, n), pa.second);
53 }
```

Line Container

Container where you can add lines of the form $kx + m$, and query maximum values at points x. All operations are $\mathcal{O}(\log(n))$. For doubles, use `inf = 1/.0` and `div(a,b) = a/b`

```
1 struct Line {
2     mutable ll k, m, p;
3     bool operator<(const Line& o) const { return k < o.k; }
4     bool operator<(ll x) const { return p < x; }
5 };
6 struct LineContainer : multiset<Line, less<>> {
7     const ll inf = LLONG_MAX;
8     ll div(ll a, ll b) { // floored division
9         return a / b - ((a ^ b) < 0 && a % b);
10     }
11     bool isect(iterator x, iterator y) {
12         if (y == end()) { x->p = inf; return false; }
13         if (x->k == y->k) x->p = x->m > y->m ? inf : -inf;
14         else x->p = div(y->m - x->m, x->k - y->k);
15         return x->p >= y->p;
16     }
17     void add(ll k, ll m) {
18         auto z = insert({k, m, 0}), y = z++, x = y;
19         while (isect(y, z)) z = erase(z);
20         if (x != begin() && isect(--x, y)) isect(x, y = erase(y));
21         while ((y = x) != begin() && (--x)->p >= y->p) isect(x, erase(y));
22     }
23     ll query(ll x) { assert(!empty());
24         auto l = *lower_bound(x);
25         return l.k * x + l.m;
26     }
27 };
```

Link Cut Tree

Represents a forest of unrooted trees. You can add and remove edges (as long as the result is still a forest), and check whether two nodes are in the same tree. All operations are amortized $\mathcal{O}(\log(n))$.

```
1   struct Node { // Splay tree. Root's pp contains tree's parent.
2       Node *p = 0, *pp = 0, *c[2];
3       bool flip = 0;
4       Node() { c[0] = c[1] = 0; fix(); }
5       void fix() {
6           if (c[0]) c[0]->p = this;
7           if (c[1]) c[1]->p = this;
8           // (+ update sum of subtree elements etc. if wanted)
9       }
10      void pushFlip() {
11          if (!flip) return;
12          flip = 0; swap(c[0], c[1]);
13          if (c[0]) c[0]->flip ^= 1;
14          if (c[1]) c[1]->flip ^= 1;
15      }
16      int up() { return p ? p->c[1] == this : -1; }
17      void rot(int i, int b) {
18          int h = i ^ b;
19          Node *x = c[i], *y = b == 2 ? x : x->c[h], *z = b ? y : x;
20          if ((y->p = p)) p->c[up()] = y;
21          c[i] = z->c[i ^ 1];
22          if (b < 2) {
23              x->c[h] = y->c[h ^ 1];
24              z->c[h ^ 1] = b ? x : this;
25          }
26          y->c[i ^ 1] = b ? this : x;
27          fix(); x->fix(); y->fix();
28          if (p) p->fix();
29          swap(pp, y->pp);
30      }
31      void splay() { /// Splay this up to the root. Always finishes without flip set.
32          for (pushFlip(); p; ) {
33              if (p->p) p->p->pushFlip();
34              p->pushFlip(); pushFlip();
35              int c1 = up(), c2 = p->up();
36              if (c2 == -1) p->rot(c1, 2);
37              else p->p->rot(c2, c1 != c2);
38          }
39      }
40      Node* first() { /// Return the min element of the subtree rooted at this, splayed to the top.
41          pushFlip();

83                  pp->c[1]->p = 0; pp->c[1]->pp = pp; }
84              pp->c[1] = u; pp->fix(); u = pp;
85          }
86          return u;
87      }
88  };
```

Graph Algorithms

Maximum Flow (Dinic's Algorithm)

Constructor takes number of nodes, call `addEdge` to add edges and `calc` to find maximum flow. To obtain the actual flow, look at positive values of `Edge::cap` only.

Time complexity: $\mathcal{O}(VE \log U)$ where $U = \max |\mathsf{cap}|$. $\mathcal{O}(\min(E^{1/2}, V^{2/3})E)$ if $U = 1$. $\mathcal{O}(\sqrt{V}E)$ for bipartite matching.

```
1   struct Dinic {
2       struct Edge {
3           int to, rev;
4           ll c, oc;
5           ll flow() { return max(oc - c, 0LL); }
6       };
7       vector<int> lvl, ptr, q;
8       vector<vector<Edge>> adj;
9       Dinic(int n) : lvl(n), ptr(n), q(n), adj(n) {}
10      void addEdge(int a, int b, ll c, ll rcap = 0) {
11          adj[a].push_back({b, (int)adj[b].size(), c, c});
12          adj[b].push_back({a, (int)adj[a].size() - 1, rcap, rcap});
13      }
14      ll dfs(int v, int t, ll f) {
15          if (v == t || !f) return f;
16          for (int& i = ptr[v]; i < adj[v].size(); i++) {
17              Edge& e = adj[v][i];
18              if (lvl[e.to] == lvl[v] + 1)
19                  if (ll p = dfs(e.to, t, min(f, e.c))) {
20                      e.c -= p, adj[e.to][e.rev].c += p;
21                      return p;
22                  }
23          }
24          return 0;
25      }
26      ll calc(int s, int t) {
27          ll flow = 0; q[0] = s;
28          for (int L = 0; L < 31; L++) do { // 'int L=30' maybe faster for random data
29              lvl = ptr = vector<int>(q.size());
30              int qi = 0, qe = lvl[s] = 1;
31              while (qi < qe && !lvl[t]) {
32                  int v = q[qi++];
33                  for (Edge e : adj[v])
34                      if (!lvl[e.to] && e.c >> (30 - L))
35                          q[qe++] = e.to, lvl[e.to] = lvl[v] + 1;
36              }
37              while (ll p = dfs(s, t, LLONG_MAX)) flow += p;
38          } while (lvl[t]);
39          return flow;
40      }
41      bool leftOfMinCut(int a) { return lvl[a] != 0; }
42  };
```

Bellman Ford

Calculates shortest paths from s in a graph that might have negative edge weights. Unreachable nodes get `dist = inf`; nodes reachable through negative-weight cycles get `dist = -inf`. Assumes $V^2 \max |w_i| < 2^{63}$. Time complexity: $\mathcal{O}(VE)$

```
const ll inf = 1LL << 62;
struct Ed {
    int a, b, w;
    int s() { return a < b ? a : -a; }
};
struct Node { ll dist = inf; int prev = -1; };
void bellmanFord(vector<Node>& nodes, vector<Ed>& eds, int s) {
    nodes[s].dist = 0;
    sort(all(eds), [] (Ed a, Ed b) { return a.s() < b.s(); });
    int lim = nodes.size() / 2 + 2;
    for(int i = 0; i < lim; i++)
        for(auto& ed : eds) {
            Node cur = nodes[ed.a], &dest = nodes[ed.b];
            if (abs(cur.dist) == inf) continue;
            ll d = cur.dist + ed.w;
            if (d < dest.dist) {
                dest.prev = ed.a;
                dest.dist = (i < lim - 1 ? d : -inf);
            }
        }
    for(int i = 0; i < lim; i++)
        for(auto& e : eds)
            if (nodes[e.a].dist == -inf)
                nodes[e.b].dist = -inf;
}
```

Floyd Warshall

Calculates all-pairs shortest path in a directed graph. As output, `m[i][j]` is set to the shortest distance between i and j, `inf` if no path, or `-inf` if the path goes through a negative-weight cycle. Time complexity: $\mathcal{O}(N^3)$.

```
from math import inf
def floydWarshall(m): # m[i][j] should be inf if i and j are not adjacent
    for i in range(len(m)):
        m[i][i] = min(m[i][i], 0)
    for k in range(len(m)):
        for i in range(len(m)):
            for j in range(len(m)):
                if m[i][k] != inf and m[k][j] != inf:
                    m[i][j] = min(m[i][j], max(m[i][k] + m[k][j], -inf))
    #only needed if weights can be negative:
    for k in range(len(m)):
        if m[k][k] < 0:
            for i in range(len(m)):
                for j in range(len(m)):
                    if m[i][k] != inf and m[k][j] != inf:
                        m[i][j] = -inf
```

```
const ll inf = 1LL << 62;
void floydWarshall(vector<vector<ll>>& m) { // m[i][j] should be inf if i and j are not adjacent
    int n = m.size();
    for(int i = 0; i < n; i++)
        m[i][i] = min(m[i][i], 0LL);
    for(int k = 0; k < n; k++)
        for(int i = 0; i < n; i++)
            for(int j = 0; j < n; j++)
                if (m[i][k] != inf && m[k][j] != inf)
                    m[i][j] = min(m[i][j], max(m[i][k] + m[k][j], -inf));
    //only needed if weights can be negative:
    for(int k = 0; k < n; k++)
        if (m[k][k] < 0)
            for(int i = 0; i < n; i++)
                for(int j = 0; j < n; j++)
                    if (m[i][k] != inf && m[k][j] != inf)
                        m[i][j] = -inf;
}
```

Biconnected Components

Finds all biconnected components in an undirected graph, and returns a list of edges in each. Time complexity: $\mathcal{O}(E + V)$. Note that a node can be in several components, and bridges are by default returned as a single-edge biconnected component.

```cpp
struct BCC {
    const vector<vector<ll>>* adj;
    vector<ll> dfsNum;
    ll nnum = 0;
    vector<pair<ll, ll>> st;
    vector<vector<pair<ll, ll>>> bccs;
    ll dfs(ll cur, ll par) {
        ll top = dfsNum[cur] = ++nnum;
        for (ll nxt : (*adj)[cur]) {
            if (nxt == par) continue;
            if (dfsNum[nxt]) {
                top = min(top, dfsNum[nxt]);
                if (dfsNum[nxt] < dfsNum[cur])
                    st.emplace_back(cur, nxt);
                continue;
            }
            ll si = st.size();
            ll up = dfs(nxt, cur);
            top = min(top, up);
            if (up == dfsNum[cur]) {
                bccs.emplace_back(st.begin() + si, st.end());
                bccs.back().emplace_back(cur, nxt);
                st.resize(si);
            } else if (up < dfsNum[cur]) {
                st.emplace_back(cur, nxt);
            } else { //the edge (cur,nxt) is a bridge
                bccs.push_back({make_pair(cur, nxt)}); //remove if bridges should not form BCCs
            }
        }
        return top;
    }
};
vector<vector<pair<ll, ll>>> findBCC(const vector<vector<ll>>& adj) {
    BCC bcc = { &adj, vector<ll>(adj.size()) };
    for (ll i = 0; i < (ll)adj.size(); i++)
        if (bcc.dfsNum[i] == 0)
            bcc.dfs(i, -1);
    return move(bcc.bccs);
}
```

Strongly Connected Components

Finds strongly connected components in a directed graph. Usage: `scc(graph, [&](vector<int>& v) { ... })}` visits all components in reverse topological order. `comp[i]` holds the component index of a node (a component only has edges to components with lower index). `ncomps` will contain the number of components. Time complexity: $\mathcal{O}(E + V)$

```cpp
vector<int> val, comp, z, cont; int Time, ncomps;
template<class G, class F> int dfs(int j, G& g, F& f) {
    int low = val[j] = ++Time, x; z.push_back(j);
    for(auto& e : g[j]) if (comp[e] < 0)
        low = min(low, val[e] ?: dfs(e,g,f));
    if (low == val[j]) {
        do {
            x = z.back(); z.pop_back();
            comp[x] = ncomps;
            cont.push_back(x);
        } while (x != j);
        f(cont); cont.clear();
        ncomps++;
    }
    return val[j] = low;
}
template<class G, class F> void scc(G& g, F f) {
    val.assign(g.size(), 0);
    comp.assign(g.size(), -1);
    Time = ncomps = 0;
    for(size_t i = 0; i < g.size(); i++)
        if (comp[i] < 0) dfs(i, g, f);
}
```

2-SAT

Calculates a valid assignment to boolean variables in a 2-SAT problem. Negated variables are represented by bit-inversions (~x). Time complexity: $\mathcal{O}(N + E)$, where N is the number of boolean variables, and E is the number of clauses.

```cpp
struct TwoSat {
    int N;
    vector<vector<int>> gr;
    vector<int> values; // 0 = false, 1 = true
    TwoSat(int n = 0) : N(n), gr(2 * n) {}
    void either(int f, int j) {
        f = max(2 * f, -1-2*f);
        j = max(2 * j, -1-2*j);
        gr[f].push_back(j ^ 1);
        gr[j].push_back(f ^ 1);
    }
    void set_value(int x) { either(x, x); }
    vector<int> val, comp, z; int time = 0;
    int dfs(int i) {
        int low = val[i] = ++time, x;
        z.push_back(i);
        for(auto& e : gr[i])
            if (!comp[e])
                low = min(low, val[e] ?: dfs(e));
        if (low == val[i]) do {
            x = z.back(); z.pop_back();
            comp[x] = low;
            if (values[x>>1] == -1)
                values[x>>1] = x&1;
        } while (x != i);
        return val[i] = low;
    }
    bool solve() {
        values.assign(N, -1);
        val.assign(2 * N, 0); comp = val;
        for (int i = 0; i < 2 * N; ++i)
            if (!comp[i])
                dfs(i);
        for (int i = 0; i < N; ++i)
            if (comp[2 * i] == comp[2 * i + 1])
                return 0;
        return 1;
    }
    /* optional */ int add_var() {
        gr.emplace_back();
        gr.emplace_back();
        return N++;
    }
    /* optional */ void at_most_one(const vector<int>& li) {
        if (li.size() <= 1) return;
        int cur = ~li[0];
        for(size_t i = 2; i < li.size(); i++) {
            int next = add_var();
            either(cur, ~li[i]);
            either(cur, next);
            either(~li[i], next);
            cur = ~next;
        }
        either(cur, ~li[1]);
    }
};
```

Usage example:

```cpp
TwoSat ts(number of boolean variables);
ts.either(0, ~3); // Var 0 is true or var 3 is false
ts.set_value(2); // Var 2 is true
ts.at_most_one({0,~1,2}); // <= 1 of vars 0, ~1 and 2 are true
ts.solve(); // Returns true iff it is solvable. ts.values holds the assigned values to the variables
```

Minimum Cost Maximum Flow

Calculates min-cost max-flow. `cap[i][j]!=cap[j][i]` is allowed; double edges are not. To obtain the actual flow, look at positive values only. Time complexity: $\mathcal{O}(E^2)$. If costs can be negative, call `setpi` before `maxflow`. Negative cost cycles are not supported.

```cpp
#include <bits/extc++.h>
const ll INF = LLONG_MAX / 4;
struct MCMF {
    int N;
    vector<vector<int>> ed, red;
    vector<vector<ll>> cap, flow, cost;
    vector<int> seen;
    vector<ll> dist, pi;
    vector<pair<int, int> > par;
    MCMF(int N) : N(N), ed(N), red(N), cap(N, vector<ll>(N)),
        flow(cap), cost(cap), seen(N), dist(N), pi(N), par(N) { }
    void addEdge(int from, int to, ll cap, ll cost) {
        this->cap[from][to] = cap;
        this->cost[from][to] = cost;
        ed[from].push_back(to);
        red[to].push_back(from);
    }
    void path(int s) {
        fill(all(seen), 0);
        fill(all(dist), INF);
        dist[s] = 0; ll di;
        __gnu_pbds::priority_queue<pair<ll, int>> q;
        vector<decltype(q)::point_iterator> its(N);
        q.push({0, s});
        auto relax = [&](int i, ll cap, ll cost, int dir) {
            ll val = di - pi[i] + cost;
            if (cap && val < dist[i]) {
                dist[i] = val;
                par[i] = {s, dir};
                if (its[i] == q.end())
                    its[i] = q.push({-dist[i], i});
                else
                    q.modify(its[i], {-dist[i], i});
            }
        };
        while (!q.empty()) {
            s = q.top().second; q.pop();
            seen[s] = 1;
            di = dist[s] + pi[s];
            for (auto& i : ed[s]) if (!seen[i])
                relax(i, cap[s][i] - flow[s][i], cost[s][i], 1);
            for (auto& i : red[s]) if (!seen[i])
                relax(i, flow[i][s], -cost[i][s], 0);
        }
        for(int i = 0; i < N; i++)
            pi[i] = min(pi[i] + dist[i], INF);
    }
    pair<ll, ll> maxflow(int s, int t) {
        ll totflow = 0, totcost = 0;
        while (path(s), seen[t]) {
            ll fl = INF;
            for (int p,r,x = t; tie(p,r) = par[x], x != s; x = p)
                fl = min(fl, r ? cap[p][x] - flow[p][x] : flow[x][p]);
            totflow += fl;
            for (int p,r,x = t; tie(p,r) = par[x], x != s; x = p) {
                if (r) flow[p][x] += fl;
                else flow[x][p] -= fl;
            }
        }
        for(int i = 0; i < N; i++)
            for(int j = 0; j < N; j++)
                totcost += cost[i][j] * flow[i][j];
        return { totflow, totcost };
    }
    void setpi(int s) { // optional, if some costs can be negative, call this before maxflow
        fill(all(pi), INF); pi[s] = 0;
        int it = N, ch = 1; ll v;
        while (ch-- && it--)
            for(int i = 0; i < N; i++) if (pi[i] != INF)
```

```
70              for(auto& to : ed[i]) if (cap[i][to])
71                  if ((v = pi[i] + cost[i][to]) < pi[to])
72                      pi[to] = v, ch = 1;
73          assert(it >= 0); // negative cost cycle
74      }
75 };
```

Weighted Bipartite Matching

Given a weighted bipartite graph, matches every node on the left with a node on the right such that no nodes are in two matchings and the sum of the edge weights is minimal.

Takes cost[N][M], where cost[i][j] = cost for L[i] to be matched with R[j] and returns (min cost, match), where L[i] is matched with R[match[i]]. Negate costs for max cost. Requires $N \le M$. Time complexity: $\mathcal{O}(N^2 M)$

```
1 pair<ll, vector<ll>> hungarian(const vector<vector<ll>> &a) {
2     if (a.empty()) return {0, {}};
3     ll n = a.size() + 1;
4     ll m = a[0].size() + 1;
5     vector<ll> u(n), v(m), p(m), ans(n - 1);
6     for (ll i = 1; i < n; i++) {
7         p[0] = i;
8         ll j0 = 0;
9         vector<ll> dist(m, LLONG_MAX), pre(m, -1);
10        vector<bool> done(m + 1);
11        do {
12            done[j0] = true;
13            ll i0 = p[j0], j1, delta = LLONG_MAX;
14            for (ll j = 1; j < m; j++) if (!done[j]) {
15                auto cur = a[i0 - 1][j - 1] - u[i0] - v[j];
16                if (cur < dist[j]) dist[j] = cur, pre[j] = j0;
17                if (dist[j] < delta) delta = dist[j], j1 = j;
18            }
19            for (ll j = 0; j < m; j++) {
20                if (done[j]) u[p[j]] += delta, v[j] -= delta;
21                else dist[j] -= delta;
22            }
23            j0 = j1;
24        } while (p[j0]);
25        while (j0) {
26            ll j1 = pre[j0];
27            p[j0] = p[j1], j0 = j1;
28        }
29    }
30    for (ll j = 1; j < m; j++) if (p[j]) ans[p[j] - 1] = j - 1;
31    return {-v[0], ans};
32 }
```

Math

Fast Mududo Operations

```
1 using ull = unsigned long long;
2 ull modmul(ull a, ull b, ull M) {
3     ll ret = a * b - M * ull(1.L / M * a * b);
4     return ret + M * (ret < 0) - M * (ret >= (ll)M);
5 }
6 ull modpow(ull b, ull e, ull mod) {
7     ull ans = 1;
8     for (; e; b = modmul(b, b, mod), e /= 2)
9         if (e & 1) ans = modmul(ans, b, mod);
10    return ans;
11 }
```

Is Prime (Miller-Rabin)

Guaranteed to work for numbers up to $7 \cdot 10^{18}$. For larger numbers, use Python and extend A randomly.

```cpp
#include "modmul.cpp"
bool isPrime(ull n) {
    if (n < 2 || n % 6 % 4 != 1)
        return (n | 1) == 3;
    ull s = __builtin_ctzll(n-1);
    for (ull a : {2, 325, 9375, 28178, 450775,
        9780504, 1795265022}) {
        ull p = modpow(a % n, n >> s, n), i = s;
        while (p != 1 && p != n - 1 && a % n && i--)
            p = modmul(p, p, n);
        if (p != n-1 && i != s) return 0;
    }
    return 1;
}
```

```python
def ctz(x): return (x & -x).bit_length() - 1
A = [2,325,9375,28178,450775,9780504,1795265022]
def isPrime(n):
    if n < 2 or n % 6 % 4 != 1:
        return (n | 1) == 3
    s = ctz(n-1)
    for a in A:
        p, i = pow(a % n, n >> s, n), s
        while p != 1 and p != n - 1 and a % n and i:
            p, i = p * p % n, i - 1
        if p != n-1 and i != s:
            return False
    return True
```

Prime Factorization (Pollard-rho)

Returns prime factors of a number, in arbitrary order.

```cpp
#include "is_prime.cpp"
ull pollard(ull n) {
    auto f = [n](ull x) {return modmul(x, x, n)+1;};
    ull x = 0, y = 0, t = 30, prd = 2, i = 1;
    while (t++ % 40 || gcd(prd, n) == 1) {
        if (x == y) x = ++i, y = f(x);
        ull q = modmul(prd, max(x,y)-min(x,y), n);
        if (q) prd = q;
        x = f(x), y = f(f(y));
    }
    return gcd(prd, n);
}
vector<ull> factor(ull n) {
    if (n == 1) return {};
    if (isPrime(n)) return {n};
    ull x = pollard(n);
    auto l = factor(x), r = factor(n / x);
    l.insert(l.end(), all(r));
    return l;
}
```

```python
from math import gcd
def pollard(n):
    f = lambda x: x * x % n + 1
    x, y, t, prd, i = 0, 0, 30, 2, 1
    while t % 40 or gcd(prd, n) == 1:
        if x == y:
            i += 1
            x, y = i, f(i)
        if q := prd * (max(x,y) - min(x,y)) % n:
            prd = q
        x, y = f(x), f(f(y))
        t += 1
    return gcd(prd, n)
def factor(n):
    if n == 1: return []
    if isPrime(n): return [n]
    x = pollard(n)
    return factor(x) + factor(n // x)
```

Extended Euclidean Algorithm

Finds the Greatest Common Divisor to the integers a and b. Also finds two integers x and y, such that $ax+by = \gcd(a,b)$. Returns a tuple of $(\gcd(a,b), x, y)$. If a and b are coprime, then x is the inverse of $a \pmod b$.

```cpp
ll extEuclid(ll a, ll b, ll& x, ll& y) {
    if (b) {
        ll d = extEuclid(b, a % b, y, x);
        return y -= a / b * x, d;
    }
    return x = 1, y = 0, a;
}
```

```python
def extEuclid(a, b):
    if b:
        d, x, y = extEuclid(b, a % b)
        return (d, y, x - a // b * y)
    return (a, 1, 0)
```

Chinese Remainder Theorem

Finds the smallest number x satisfying a system of congruences, each in the form $x \equiv r_i \pmod{m_i}$. All pairs of m_i must be coprime. eq is a list of tuples describing the equations, the i:th of which should be (r_i, m_i).

```cpp
//no overflow if the product of all eq.second < 2^62
ll crt(const vector<pair<ll, ll>>& eq) {
    ll p = 1, res = 0;
    for (auto e : eq) p *= e.second;
    for (auto e : eq) {
        ll pp = p / e.second, ppi, y;
        extEuclid(pp, e.second, ppi, y);
        res = (res + e.first * ppi * pp) % p;
    }
    return res;
}
```

```python
def crt(eq):
    p, res = 1, 0
    for rem, md in eq:
        p *= md
    for rem, md in eq:
        pp = p // md
        res = (res + rem*extEuclid(pp, md)[1]*pp) % p
    return res
```

Fraction Binary Search

Given f and N, finds the smallest fraction $p/q \in [0, 1]$ such that $f(p/q)$ is true, and $p, q \leq N$.

```cpp
struct Frac { ll p, q; };
template<class F> Frac fractionBinarySearch(F f, ll N) {
    bool dir = 1, A = 1, B = 1;
    Frac lo{0, 1}, hi{1, 1}; // Set hi to 1/0 to search (0, N]
    if (f(lo)) return lo;
    assert(f(hi));
    while (A || B) {
        ll adv = 0, step = 1; // move hi if dir, else lo
        for (ll si = 0; step; (step *= 2) >>= si) {
            adv += step;
            Frac mid{lo.p * adv + hi.p, lo.q * adv + hi.q};
            if (abs(mid.p) > N || mid.q > N || dir == !f(mid))
                adv -= step; si = 2;
        }
        hi.p += lo.p * adv;
        hi.q += lo.q * adv;
        dir = !dir;
        swap(lo, hi);
        A = B; B = !!adv;
    }
    return dir ? hi : lo;
}
```

Solve Linear System of Equations

Solves $Ax = b$. If there are multiple solutions, an arbitrary one is returned. Returns rank, or -1 if no solutions. Time complexity: $\mathcal{O}(n^2 m)$

```cpp
int solveLinear(vector<vector<double>> A, vector<double> b, vector<double>& x) {
    const double eps = 1e-12;
    int n = A.size(), m = x.size(), rank = 0, br, bc;
    if (n) assert((int)A[0].size() == m);
    vector<int> col(m); iota(all(col), 0);
    for(int i = 0; i < n; i++) {
        double v, bv = 0;
        for(int r = i; r < n; ++r) for(int c = i; c < m; c++)
            if ((v = fabs(A[r][c])) > bv)
                br = r, bc = c, bv = v;
        if (bv <= eps) {
            for(int j = i; j < n; j++)
                if (fabs(b[j]) > eps) return -1;
            break;
        }
        swap(A[i], A[br]);
        swap(b[i], b[br]);
        swap(col[i], col[bc]);
        for(int j = 0; j < n; j++)
            swap(A[j][i], A[j][bc]);
        bv = 1 / A[i][i];
        for(int j = i + 1; j < n; j++) {
            double fac = A[j][i] * bv;
            b[j] -= fac * b[i];
            for(int k = i+1; k < (m); ++k)
                A[j][k] -= fac*A[i][k];
        }
        rank++;
    }
    x.assign(m, 0);
    for (int i = rank; i--;) {
        b[i] /= A[i][i];
        x[col[i]] = b[i];
        for (int j = 0; j < i; j++)
            b[j] -= A[j][i] * b[i];
    }
    return rank;
}
```

Matrix Inverse

Invert matrix A. Returns rank; result is stored in A unless singular (rank < n). Time complexity: $\mathcal{O}(n^3)$

```cpp
ll matInv(vector<vector<double>>& A) {
    ll n = A.size();
    vector<ll> col(n);
    vector<vector<double>> tmp(n, vector<double>(n));
    for (ll i = 0; i < n; i++) {
        tmp[i][i] = 1;
        col[i] = i;
    }
    for (ll i = 0; i < n; i++) {
        ll r = i, c = i;
        for (ll j = i; j < n; j++)
            for (ll k = i; j < n; j++)
                if (fabs(A[j][k]) > fabs(A[r][c]))
                    r = j, c = k;
        if (fabs(A[r][c]) < 1e-12) return i;
        A[i].swap(A[r]); tmp[i].swap(tmp[r]);
        for (ll j = 0; j < n; j++)
            swap(A[j][i], A[j][c]), swap(tmp[j][i], tmp[j][c]);
        swap(col[i], col[c]);
        double v = A[i][i];
        for (ll j = i+1; j < n; j++) {
            double f = A[j][i] / v;
            A[j][i] = 0;
            for (ll k = i+1; k < n; k++) A[j][k] -= f*A[i][k];
            for (ll k = 0; k < n; k++) tmp[j][k] -= f*tmp[i][k];
        }
        for (ll j = i+1; j < n; j++) A[i][j] /= v;
        for (ll j = 0; j < n; j++) tmp[i][j] /= v;
        A[i][i] = 1;
    }
    for (ll i = n-1; i > 0; --i) {
        for (ll j = 0; j < i; j++) {
            double v = A[j][i];
            for (ll k = 0; k < n; k++) tmp[j][k] -= v*tmp[i][k];
        }
    }
    for (ll i = 0; i < n; i++)
        for (ll j = 0; j < n; j++)
            A[col[i]][col[j]] = tmp[i][j];
    return n;
}
```

Polynomial Roots

Finds the real roots of a polynomial. Time complexity: $\mathcal{O}(n^2 \log(1/\epsilon))$.
Usage (solves $x^2 - 3x + 2 = 0$): `poly_roots({{ 2, -3, 1 }},-1e9,1e9)`

```cpp
struct Poly {
    vector<double> a;
    double operator()(double x) const {
        double val = 0;
        for(int i = a.size(); i--;)
            (val *= x) += a[i];
        return val;
    }
    void diff() {
        for (size_t i = 1; i < a.size(); i++)
            a[i - 1] = i * a[i];
        a.pop_back();
    }
};
vector<double> poly_roots(Poly p, double xmin, double xmax) {
    if (p.a.size() == 2) return { -p.a[0] / p.a[1] };
    vector<double> ret;
    Poly der = p;
    der.diff();
    auto dr = poly_roots(der, xmin, xmax);
    dr.push_back(xmin - 1);
    dr.push_back(xmax + 1);
    sort(all(dr));
```

```
24      for (size_t i = 0; i < dr.size() - 1; i++) {
25          double l = dr[i], h = dr[i + 1];
26          bool sign = p(l) > 0;
27          if (sign ^ (p(h) > 0)) {
28              for (int it = 0; it < 60; it++) {
29                  double m = (l + h) / 2, f = p(m);
30                  if ((f <= 0) ^ sign) l = m;
31                  else h = m;
32              }
33              ret.push_back((l + h) / 2);
34          }
35      }
36      return ret;
37  }
```

FFT

`fft(a)` computes $\hat{f}(k) = \sum_x a[x] \exp(2\pi i \cdot kx/N)$ for all k. Useful for convolution: `conv(a, b)=c`, where $c[x] = \sum a[i]b[x-i]$.
Rounding is safe if $(\sum a_i^2 + \sum b_i^2) \log_2 N < 9 \cdot 10^{14}$ (in practice 10^{16}; higher for random inputs).

Time complexity: $\mathcal{O}(N \log N)$ with $N = |A| + |B|$ (about $1s$ for $N = 4 \cdot 10^6$)

```
1   typedef complex<double> C;
2   void fft(vector<C>& a) {
3       int n = a.size(), L = 31 - __builtin_clz(n);
4       static vector<complex<long double>> R(2, 1);
5       static vector<C> rt(2, 1);  // (^ 10% faster if double)
6       for (int k = 2; k < n; k *= 2) {
7           R.resize(n); rt.resize(n);
8           auto x = polar(1.0L, M_PIl / k);
9           for (int i = k; i < 2 * k; i++)
10              rt[i] = R[i] = i & 1 ? R[i / 2] * x : R[i / 2];
11      }
12      vector<int> rev(n);
13      for (int i = 0; i < n; i++)
14          rev[i] = (rev[i / 2] | (i & 1) << L) / 2;
15      for (int i = 0; i < n; i++)
16          if (i < rev[i]) swap(a[i], a[rev[i]]);
17      for (int k = 1; k < n; k *= 2)
18          for (int i = 0; i < n; i += 2 * k)
19              for(int j = 0; j < k; j++) {
20                  auto x = (double*)&rt[j + k], y = (double*)&a[i + j + k];
21                  C z(x[0] * y[0] - x[1] * y[1], x[0] * y[1] + x[1] * y[0]);
22                  a[i + j + k] = a[i + j] - z;
23                  a[i + j] += z;
24              }
25  }
26  vector<double> conv(const vector<double>& a, const vector<double>& b) {
27      if (a.empty() || b.empty()) return { };
28      vector<double> res(a.size() + a.size() - 1);
29      int L = 32 - __builtin_clz(res.size()), n = 1 << L;
30      vector<C> in(n), out(n);
31      copy(all(a), begin(in));
32      for (size_t i = 0; i < a.size(); i++)
33          in[i].imag(b[i]);
34      fft(in);
35      for (C& x : in) x *= x;
36      for (int i = 0; i < n; i++)
37          out[i] = in[-i & (n - 1)] - conj(in[i]);
38      fft(out);
39      for (size_t i = 0; i < res.size(); i++)
40          res[i] = imag(out[i]) / (4 * n);
41      return res;
42  }
```

ModFFT

`fft(a)` computes $\hat{f}(k) = \sum_x a[x]g^{xk}$ for all k, where $g = \text{root}^{(M-1)/N}$. N must be a power of 2.

For conv, M should be of the form $2^a b + 1$, and the convolution result should have size at most 2^a. Inputs must be in $[0, M)$.

```cpp
constexpr ll M = 998244353, root = 62;
ll modpow(ll b, ll e) {
    ll ans = 1;
    for (; e; b = b * b % M, e /= 2)
        if (e & 1) ans = ans * b % M;
    return ans;
}
void fft(vector<ll> &a) {
    ll n = a.size(), L = 31 - __builtin_clz(n);
    static vector<ll> rt(2, 1);
    for (static ll k = 2, s = 2; k < n; k *= 2, s++) {
        rt.resize(n);
        ll z[] = {1, modpow(root, M >> s)};
        for (ll i = k; i < 2 * k; i++)
            rt[i] = rt[i / 2] * z[i & 1] % M;
    }
    vector<ll> rev(n);
    for (ll i = 0; i < n; i++)
        rev[i] = (rev[i / 2] | (i & 1) << L) / 2;
    for (ll i = 0; i < n; i++)
        if (i < rev[i])
            swap(a[i], a[rev[i]]);
    for (ll k = 1; k < n; k *= 2)
        for (ll i = 0; i < n; i += 2 * k) for (ll j = 0; j < k; j++) {
            ll z = rt[j + k] * a[i + j + k] % M, &ai = a[i + j];
            a[i + j + k] = ai - z + (z > ai ? M : 0);
            ai += (ai + z >= M ? z - M : z);
        }
}
vector<ll> conv(const vector<ll> &a, const vector<ll> &b) {
    if (a.empty() || b.empty()) return {};
    ll s = (ll)(a.size() + b.size()) - 1;
    ll B = 32 - __builtin_clz(s);
    ll n = 1 << B;
    ll inv = modpow(n, M - 2);
    vector<ll> L(a), R(b), out(n);
    L.resize(n); R.resize(n);
    fft(L); fft(R);
    for (ll i = 0; i < n; i++)
        out[-i & (n - 1)] = (ll)L[i] * R[i] % M * inv % M;
    fft(out);
    return { out.begin(), out.begin() + s };
}
```
